# Website Construction

(PHP Includes)

Server-side Includes (SSI)

- Reduce the amount of code you duplicate in webpages
- "Include" contents
- Example
  - Include the HTML code for a common header, sidebar, footer, or whatever, that appears on all pages

How it works

The normal process is:

1. Request
2. Locate
3. Response

With server-side scripts, there is a slightly different process

1. Request
2. Locate
3. Read
4. Execute
5. Rebuild
6. Response

the include process

Request

Response

Remember: the Web uses a client/server network architecture

When Will the Server Look For scripts?

The "trigger"

- On the webserver: Apache with PHP so…

- ".php" not ".html"

- The *include* command

Example:

```
<?php include "inc/more-content.inc"; ?>
```

"Including" - an Example

On the web server…

index.php

```
<div>Just some regular HTML here</div>

<?php include "inc/more-content.inc"; ?>

<div>And then some more regular HTML,
whatever</div>
```

inc/more-content.inc

```
<div> Blah blah blah, more
content here!</div>
```

index.php

What shows up in the web browser…

```
<div>Just some regular HTML here</div>

<div> Blah blah blah, more content here!</div>

<div>And then some more regular HTML,
whatever</div>
```

Summary of PHP includes

- Using PHP? Then the file extension MUST be: .php
  - Example: index.php

- If using a PHP *include* statement: the file extension of the included file can be whatever you want
  - The industry standard is: .inc
  - Example: footer.inc

- The location of your include files: can be anywhere in the file system
  - The industry standard is to put them into a subfolder named inc/
